

THE PIXEL CONSTANT

Self-referential outer/inner fixed point for observation

1. OUTSIDE PIXEL AREA

Declared Screen Geometry

Boundary cell area in Planck units:

$$P = a_{\text{cell}} / \ell_P^2$$

This is the outside screen cell measured as an area ratio.

2. FIXED-POINT CLOSURE

Step A: Build EM readout

$$A_T(P)$$

Step B: Close outer/inner map

$$P = \varphi + \sqrt{\pi} / A_T(P)$$

Step C: Fixed point (gauge width)

$$P^* = 1.6309682414$$

Step D: Read observation strength

$$\alpha(P^*) = 1 / 137.035660$$

Measured α is used only for comparison.

3. OUTPUT: OBSERVATION PIXEL

Fixed-point value:

$$P^* = 1.6309682414$$

Outside cell area matches inside electromagnetic readout.

P links the simulating-side pixel area to electromagnetic observation in the simulated universe.

The fixed point gives $1/\alpha = 137.035660$; the measured 137.035999 also holds the low-energy quark term, open at 2.5 parts per million.
